

I built an AI Summarization Tool...

Then I tested it like a QA.

It didn't behave the way I expected.

The feature is simple:

01

Input

Long text is passed to the model.

02

Output

A short summary is returned.

03

First impression

Looks correct. Feels correct.

3 / 9

But is it reliable?

That's what I wanted to test.

Not just accuracy

Also behavior

Test 1: Same Input

I ran the same input **multiple times**.

Run 1

Summary A

Run 2

Summary B

Run 3

Summary C

Result: Same summaries each time. Consistent.

5 / 9

Test 2: Slight Changes

I changed wording slightly. **Same meaning.**

Input A

"The report showed growth"

Input B

"Growth was shown in the report"

Finding: Same output. Highly positive.

6 / 9

Test 3: Long vs Short Text

Summarizing longer content revealed a critical gap:

Important details were missing.

⊗ **Information loss.** The model silently dropped key facts.

7 / 9

Here's the shift:

Traditional QA

Is it **correct**?

AI QA

Is it correct?

Is it **reliable**? Is it **consistent**?

8 / 9

AI doesn't fail like normal systems

- It **varies**
Outputs shift across runs
- It **drifts**
Behavior changes over time
- It **confuses**
Subtle inputs cause big swings

QA for AI is different

Traditional QA

Validate **outputs**

AI QA

Evaluate **output + behavior**

We don't only validate outputs.

We evaluate behavior.

Follow for more QA/AI insights.
